

Generation-based ABC: every generation waits for its slowest simulation

Generation-free ABC (ours): the proposal is rebuilt after every arrival, nobody waits

The barrier costs the straggler factor $\mathbb{E}[\max_{i \leq W} T_i] / \mu$: $1\times$ for a homogeneous simulator, $2.3\times$ for the workload drawn here (76 against 32 simulations), up to $400\times$ measured. Removing the generation removes the factor, and the reported posterior stays a pure function of the evaluated history.
